Project Report: Personal Finance Tracker Using SQL

---

1. Introduction

In today's fast-paced world, managing personal finances has become an essential aspect of everyday life. With increasing expenses, diverse sources of income, and the need for saving and budgeting, individuals often struggle to keep track of their financial activities. Traditional methods such as manual record-keeping or spreadsheets are often inefficient, error-prone, and difficult to maintain over time.

To address this challenge, this project introduces a **Personal Finance Tracker** powered by **Structured Query Language (SQL)**. The primary goal is to provide a structured and reliable system that enables users to log their income and expenses, categorize transactions, and generate detailed summaries and insights. By leveraging the power of relational databases, this system ensures accurate data management and efficient retrieval of financial information.

The project involves the design and implementation of a well-structured database that stores user profiles, transaction records, and category information. Through SQL queries, users can perform key operations such as adding new transactions, editing or deleting existing records, and generating time-based financial reports. This SQL-based solution emphasizes data consistency, scalability, and analytical capability, making it a foundational step towards building more advanced financial applications.

Ultimately, this project not only demonstrates core database concepts and SQL proficiency but also offers a practical tool that can assist individuals in making informed financial decisions, promoting better budgeting, saving habits, and financial discipline.

---

2. Abstract

In the modern age of digital finance, effectively tracking personal income and expenses is crucial for financial stability and informed decision-making. This project, titled **"Personal Finance Tracker Using SQL"**, presents a database-driven solution for managing and analyzing personal financial data. The core objective is to design and implement a relational database system that allows users to record, categorize, and monitor their financial transactions.

Using **Structured Query Language (SQL)**, the system enables users to input income and expense records, organize them by category, and generate comprehensive reports such as monthly summaries and spending comparisons. The project consists of three primary data entities: **Users**, **Categories**, and **Transactions**, each modeled in a normalized schema to ensure data integrity and efficiency.

Key functionalities include the ability to add, modify, and delete transactions, filter them by date or category, and calculate total income versus expenses. Analytical queries provide users with meaningful insights into their financial behavior. The project serves as a practical

demonstration of how database technologies can be applied to solve real-world personal finance challenges.

This solution, while currently command-line and SQL-driven, lays the foundation for further expansion into full-featured applications with GUI or mobile interfaces, integration with financial APIs, and data visualization for enhanced user experience.

---

3. Tools Used

- **MySQL Workbench** – Development environment for executing SQL queries and managing schema.

---

4. Steps Involved in Building the Project

1. **Database Design**: Defined schema with four interconnected tables: Users, Categories, Income, and Expenses. Relationships were established using primary and foreign keys to maintain data integrity.
2. **Data Insertion**: Populated the tables with dummy records including two users, five categories, and multiple income and expense transactions spanning various dates.
3. **Query Implementation**:
    - Wrote SQL queries to summarize monthly expenses using GROUP BY and DATE_FORMAT.
    - Created category-wise reports for individual users.
    - Tracked income sources and their monthly totals.
4. **View Creation**: A SQL view (MonthlyBalance) was created to show monthly balances per user (income minus expenses), providing insight into savings and overspending.
5. **Report Generation**: Ran the queries in MySQL Workbench and exported results as .csv files to simulate report sharing and financial analysis.
6. **Project Packaging**: All SQL files and reports were organized and uploaded to GitHub for submission.

---

5. Conclusion

The Personal Finance Tracker project showcases the practical use of SQL in managing structured financial data. It offers insights into a user's financial behavior through summary queries and custom views. By combining data modeling, query writing, and reporting, this project lays a strong foundation for backend systems used in financial apps and services.

This SQL-based solution can be enhanced further by adding a web interface or integrating machine learning techniques for financial forecasting. However, even in its current form, it provides a robust model for budgeting, reporting, and spending analysis. Through this project, I gained hands-on experience in relational databases, data aggregation, and business logic implementation using SQL — all valuable skills for backend development and data roles.
